Unlocking the Secrets: A Comprehensive Guide on How to Solve Equations in Algebra

Ever felt a pang of dread when faced with a string of letters and numbers that just don't seem to make sense? You're not alone! For many, algebra can feel like a secret language. But here's the exciting truth: solving equations in algebra isn't about deciphering ancient riddles; it's about learning a set of logical steps and principles that, once mastered, can unlock a powerful way of thinking and problem-solving. Think of an equation as a balanced scale. Whatever you do to one side, you *must* do to the other to keep it balanced. This fundamental concept is the bedrock of solving algebraic equations. Whether you're dealing with simple linear equations or more complex quadratic expressions, the goal is always to isolate the unknown variable (usually represented by a letter like 'x', 'y', or 'a') and discover its value. In this comprehensive guide, we'll break down the process of solving equations in algebra into manageable steps. We'll cover the essential tools, explore different types of equations, and equip you with the

confidence to tackle them head-on. So, grab a pen and paper, and let's dive into the fascinating world of algebraic problem-solving!

The Building Blocks: Understanding the Anatomy of an Equation

Before we start solving, let's get acquainted with the key components of an algebraic equation:

- * **Variables:** These are the letters (like x , y , a , b) that represent unknown quantities. They're the stars of the show, and our mission is to find their values.
- * **Constants:** These are the fixed numbers (like 5 , -3 , $1/2$) that have a definite value.
- * **Coefficients:** This is the number that multiplies a variable (e.g., in $3x$, '3' is the coefficient of ' x ').
- * **Terms:** These are the parts of an equation separated by addition or subtraction signs (e.g., in $2x + 5 = 11$, ' $2x$ ' and ' 5 ' are terms on one side, and ' 11 ' is a term on the other).
- * **The Equals Sign ($=$):** This is the crucial symbol that signifies that the expression on the left side has the same value as the expression on the right side. It's the point of balance we talked about.

The Golden Rule: Keeping the Equation Balanced

Remember our balanced scale analogy? This is the most important principle in algebra. Whatever operation you perform on one side of the equation, you must perform the *exact same operation* on the other side. This ensures the equality remains true. The primary operations we'll use are:

- * **Addition:** Adding the same number to both sides.
- * **Subtraction:** Subtracting the same number from both sides.
- * **Multiplication:** Multiplying both sides by the same non-zero number.
- * **Division:** Dividing both sides by the same non-zero number.

These are your trusty tools for manipulating equations and isolating the variable.

Solving Basic Linear Equations: The Foundation

Linear equations are the simplest type, where the highest power of the variable is 1. They typically look like $ax + b = c$, where 'a', 'b', and 'c' are constants. The goal is to get the variable 'x' all by itself on one side of the equals sign.

Step-by-Step: A Classic Example

Let's take a look at a common scenario: solving for 'x' in the equation: $3x + 5 = 14$. Here's how we break it down:

- 1. Isolate the term with the variable:** Our variable 'x' is currently part of the term '3x'. To get this term alone, we need to get rid of the '+ 5'. The opposite of adding 5 is subtracting 5. So, we subtract 5 from **both** sides of the equation: $3x + 5 - 5 = 14 - 5$ $3x = 9$
- 2. Isolate the variable itself:** Now we have '3x', which means '3 multiplied by x'. To get 'x' by itself, we need to undo the multiplication. The opposite of multiplying by 3 is dividing by 3. So, we divide **both** sides of the equation by 3: $3x / 3 = 9 / 3$ $x = 3$
- And there you have it! The solution is $x = 3$.** To check your answer, plug $x = 3$ back into the original equation: $3(3) + 5 = 9 + 5 = 14$. Since $14 = 14$, our solution is correct! This checking process, often called verification, is a vital part of solving equations to ensure accuracy.

Dealing with Variables on Both Sides

Sometimes, you'll encounter equations where the variable appears on both sides of the equals sign, like: $5x - 3 = 2x + 9$. The strategy here is to gather all the variable terms on one side and all the constant terms on the other.

- 1. Move variable terms:** Let's move the '2x' from the right side to the left. Since it's currently being added, we subtract '2x' from both sides: $5x - 3 - 2x = 2x + 9 - 2x$ $3x - 3 = 9$
- 2. Move constant terms:** Now, let's move the '-3' from the left side to the right. The opposite of subtracting 3 is adding 3. So, we add 3 to both sides: $3x - 3 + 3 = 9 + 3$ $3x = 12$
- 3. Isolate the variable:** Finally, divide both sides by

3: $3x / 3 = 12 / 3$ $x = 4$ Again, verify by plugging $x = 4$ back into the original equation: $5(4) - 3 = 20 - 3 = 17$ $2(4) + 9 = 8 + 9 = 17$ Since $17 = 17$, our solution is correct.

Beyond the Basics: Solving Equations with Parentheses and Fractions

As you progress in algebra, you'll encounter equations that require a few extra steps.

Conquering Parentheses: The Distributive Property

When an equation contains parentheses, you often need to use the distributive property first. This means multiplying the number outside the parentheses by each term inside the parentheses. Consider: **$2(x + 4) = 10$** 1. **Distribute:** Multiply 2 by 'x' and 2 by '4': $2 \cdot x + 2 \cdot 4 = 10$ $2x + 8 = 10$ 2. **Solve the linear equation:** Now it's a familiar linear equation. Subtract 8 from both sides: $2x + 8 - 8 = 10 - 8$ $2x = 2$ 3. **Isolate the variable:** Divide both sides by 2: $2x / 2 = 2 / 2$ $x = 1$

Taming Fractions: Clearing the Denominators

Equations with fractions can look intimidating, but they become much simpler once you "clear" the denominators. The key is to multiply the *entire* equation by the least common multiple (LCM) of all the denominators. Let's solve: **$(x/2) + (x/3) = 5$** 1. **Find the LCM:** The denominators are 2 and 3. The LCM of 2 and 3 is 6. 2. **Multiply by the LCM:** Multiply *every term* on both sides of the equation by 6: $6 \cdot (x/2) + 6 \cdot (x/3) = 6 \cdot 5$ 3. **Simplify:** $(6x)/2 + (6x)/3 = 30$ $3x + 2x = 30$ 4. **Combine like terms:** $5x = 30$ 5. **Isolate the variable:** Divide both sides by 5: $5x / 5 = 30 / 5$ $x = 6$ This process effectively eliminates the fractions,

leaving you with a simpler equation to solve.

Introducing Quadratic Equations: A New Frontier

Quadratic equations are equations where the highest power of the variable is 2. They typically take the form $ax^2 + bx + c = 0$. While linear equations are solved with straightforward isolation, quadratic equations often require different techniques.

Factoring: Deconstructing the Expression

Factoring is a powerful method for solving quadratic equations when the expression can be broken down into a product of two binomials. The principle is that if a product of factors equals zero, then at least one of the factors must be zero. Consider: $x^2 - 5x + 6 = 0$ 1. **Factor the quadratic:** We need to find two numbers that multiply to +6 and add up to -5. These numbers are -2 and -3. So, we can factor the equation as: $(x - 2)(x - 3) = 0$ 2. **Set each factor to zero:** $x - 2 = 0 \Rightarrow x = 2$ $x - 3 = 0 \Rightarrow x = 3$ So, the solutions (or roots) of this quadratic equation are $x = 2$ and $x = 3$.

The Quadratic Formula: Your Universal Solver

Not all quadratic equations can be easily factored. That's where the quadratic formula comes in – it's a foolproof method that works for *any* quadratic equation. For an equation in the form $ax^2 + bx + c = 0$, the solutions are given by:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Let's use the formula to solve our previous example: $x^2 - 5x + 6 = 0$. Here, $a = 1$, $b = -5$, and $c = 6$. 1. **Substitute the values into the formula:** $x = \frac{-(-5) \pm \sqrt{(-5)^2 - 4 * 1 * 6}}{2 * 1}$ 2. **Simplify:** $x = \frac{[5 \pm \sqrt{(25 - 24)}]}{2}$ $x = \frac{[5 \pm \sqrt{1}]}{2}$ $x =$

$[5 \pm 1] / 2$ 3. **Calculate the two possible solutions:** $x = (5 + 1) / 2 = 6 / 2 = 3$
 $x = (5 - 1) / 2 = 4 / 2 = 2$ The quadratic formula gives us the same solutions: $x = 3$ and $x = 2$.

clear understanding of the principles, you'll find that solving equations in algebra is not only achievable but also incredibly rewarding. Happy solving!

Solving equations lies at the heart of algebra, serving as a fundamental skill that unlocks deeper mathematical understanding and problem-solving capability. At its core, solving an equation means finding the value(s) of the unknown variable that make both sides of the equation equal. This process not only reveals numerical solutions but also strengthens logical reasoning and analytical thinking. Whether you're working with linear equations, quadratic expressions, or systems of equations, mastering the underlying principles enables students and professionals alike to tackle increasingly complex mathematical challenges with confidence.

Understanding the Essence of Equation

Solving The process of solving equations

hinges on the principle of balance: any

operation applied to one side of the equation

must be mirrored on the other to preserve

equality. This balance ensures that

transformations such as addition, subtraction,

multiplication, or division yield valid results

without altering the solution set. Solving

begins by simplifying both sides—combining

like terms, eliminating parentheses, and

isolating the variable. For instance, in a linear equation like $3x + 5 = 20$, the goal is to isolate x by first subtracting 5 from both sides, resulting in $3x = 15$, followed by dividing both sides by 3 to reveal $x = 5$. This step-by-step refinement builds clarity and precision.

Key Insights and Problem-Solving Strategies

Beyond basic arithmetic, solving equations demands strategic thinking. Recognizing patterns—such as recognizing a perfect square trinomial or a difference of cubes—can simplify the path to solutions. Factoring, substitution, and the application of the quadratic formula are powerful tools when faced with higher-degree equations. Equally important is understanding when to apply inverse operations strategically: moving constants to one side and coefficients to the other ensures systematic isolation of the

variable. Equally critical is checking solutions by substituting them back into the original equation, a practice that verifies correctness and builds trust in the solution process.

Real-World Applications and Practical Value

The ability to solve equations transcends the classroom; it is indispensable in engineering, physics, economics, and everyday decision-making. Engineers use algebraic solutions to model structural loads and optimize designs. Economists rely on equations to determine break-even points and forecast market behaviors. In daily life, from calculating loan payments to balancing budgets, algebraic thinking provides clarity and control. These applications underscore that solving equations is not merely an academic exercise but a vital competency that enhances problem-solving across disciplines and real-

world contexts.

Benefits of Mastering Algebraic Equation Solving Developing fluency in solving equations cultivates discipline in logical reasoning and boosts cognitive flexibility. It strengthens pattern recognition, improves mental agility, and fosters patience in navigating complex problems. Students who grasp these concepts early gain a foundation that makes advanced mathematics—such as calculus and linear algebra—more accessible and less intimidating. Moreover, the problem-solving mindset developed through equation solving extends beyond math, equipping learners to approach challenges methodically and creatively in any field.

The Future of Equation Solving in a Digital Age As technology advances, the role of

equation solving evolves, yet its core importance remains unchanged. While calculators and symbolic computation software streamline calculations, understanding the underlying logic ensures users interpret results accurately and discern when approximations or numerical methods are appropriate. Emerging fields like artificial intelligence and data science increasingly rely on algebraic foundations to build models and analyze patterns, making equation solving an enduring skill. Looking ahead, cultivating both computational fluency and conceptual mastery will empower individuals to navigate an increasingly quantitative world with confidence and insight. Solving equations is a timeless pillar of mathematical literacy, offering practical tools and intellectual growth. By embracing its principles, strategies, and applications,

learners unlock not just numerical answers, but a deeper understanding of the logical structure that governs both abstract and real-world phenomena.

We'll cover essential concepts like inverse operations, the properties of equality, and strategies for simplifying expressions, all crucial for effective equation solving.

Understanding how to solve equations in algebra is not just about memorizing steps; it's about grasping the underlying principles that make these operations work.

The Foundational Principles of Solving Equations

Before we dive into specific equation types, it's vital to understand the bedrock principles that govern all equation solving. These principles ensure that we maintain the balance of the equation, meaning that whatever operation we perform on one side, we must perform the exact same operation on the other side.

The Golden Rule: Maintaining Balance

Imagine an equation as a perfectly balanced scale. The equals sign ($=$) represents the fulcrum, and the expressions on either side represent the weights. To keep the scale balanced, any weight you add or remove from one side must be mirrored on the other. In algebra, this translates to the fundamental properties of equality:

- 1. Addition Property of Equality:** If $(a = b)$, then $(a + c = b + c)$. You can add the same number or expression to both sides of an equation without changing its validity.
- 2. Subtraction Property of Equality:** If $(a = b)$, then $(a - c = b - c)$. Similarly, you can subtract the same number or expression from both sides.
- 3. Multiplication Property of Equality:** If $(a = b)$, then $(ac = bc)$. You can multiply both sides by the same non-zero number or expression.
- 4. Division Property of Equality:** If $(a = b)$ and $(c \neq 0)$, then $(a/c = b/c)$. You can divide both sides by the same non-zero number or expression.

These properties are your primary tools for isolating the variable. The goal is always to undo the operations that are currently being applied to the variable.

Inverse Operations: The Key to Unlocking Variables

Every mathematical operation has an inverse operation that "undoes" it. Understanding these pairs is crucial for strategic equation solving:

- 1. Addition is undone by Subtraction.**
- 2. Subtraction is undone by Addition.**
- 3. Multiplication is undone by Division.**
- 4. Division is undone by Multiplication.**
- 5. Squaring a number is undone by taking the square root.**
- 6. Taking the square root is undone by squaring the number.**

By applying the appropriate inverse operation to both sides of the equation, you systematically strip away the numbers and operations surrounding the variable, ultimately leading to its isolation.

Solving Linear Equations: The Building Blocks of Algebra

Linear equations are the simplest type of algebraic equation, characterized by variables raised to the power of one. Their solutions represent a single point on a number line or a straight line on a graph. Mastering these will provide a solid foundation for more complex algebraic challenges.

One-Step Linear Equations

These are the most basic and involve a single operation applied to the variable. For example:

1. To solve $(x + 5 = 12)$: The variable (x) has 5 added to it. To isolate (x) , we subtract 5 from both sides: $(x + 5 - 5 = 12 - 5)$, which simplifies to $(x = 7)$.
2. To solve $(y - 3 = 9)$: The variable (y) has 3 subtracted from it. To isolate (y) , we add 3

to both sides: $(y - 3 + 3 = 9 + 3)$, resulting in $(y = 12)$.

3. To solve $(4z = 20)$: The variable (z) is multiplied by 4. To isolate (z) , we divide both sides by 4: $(4z / 4 = 20 / 4)$, giving us $(z = 5)$.

4. To solve $(w / 2 = 7)$: The variable (w) is divided by 2. To isolate (w) , we multiply both sides by 2: $((w / 2) * 2 = 7 * 2)$, leading to $(w = 14)$.

Two-Step Linear Equations

These equations involve two operations applied to the variable. The key here is to address the operations in the reverse order of operations (PEMDAS/BODMAS). Typically, you'll deal with addition/subtraction first, followed by multiplication/division.

Example: Solve $(2x + 3 = 11)$

1. Undo addition/subtraction first: Subtract 3

from both sides: $(2x + 3 - 3 = 11 - 3)$, which simplifies to $(2x = 8)$.

2. Undo multiplication/division next: Divide both sides by 2: $(2x / 2 = 8 / 2)$, resulting in $(x = 4)$.

Multi-Step Linear Equations

These equations might involve parentheses, combining like terms, variables on both sides, or fractions. The general strategy remains the same: simplify each side as much as possible, then use inverse operations to isolate the variable.

Simplifying Expressions and Combining Like Terms

Before you begin isolating the variable, it's often necessary to simplify expressions on either side of the equals sign. This includes:

1. Distributive Property: Use this to remove

parentheses. For example, in $3(x + 2) = 15$, distribute the 3 to get $3x + 6 = 15$.

2. **Combining Like Terms:** Combine terms with the same variable and the same exponent. For example, in $5x + 2x - 3 = 11$, combine $5x$ and $2x$ to get $7x - 3 = 11$.

Equations with Variables on Both Sides

When variables appear on both sides of the equation, your first step should be to move all variable terms to one side and all constant terms to the other. It doesn't matter which side you choose for the variables, but it's often easier to move them to the side that will result in a positive coefficient for the variable.

Example: Solve $5x - 2 = 2x + 7$

1. **Move variable terms to one side:** Subtract $2x$ from both sides: $5x - 2x - 2 = 2x - 2x + 7$, which simplifies to $3x - 2 = 7$.
2. **Now you have a two-step equation:** Add 2 to

both sides: $(3x - 2 + 2 = 7 + 2)$, resulting in $(3x = 9)$.

- 3. Isolate the variable: Divide both sides by 3:**
 $(3x / 3 = 9 / 3)$, giving you $(x = 3)$.

Equations with Fractions

Equations involving fractions can be intimidating, but they can be simplified by eliminating the fractions. The most effective way to do this is by multiplying both sides of the equation by the least common multiple (LCM) of the denominators. This process is often referred to as clearing the denominators.

Example: Solve $(\frac{1}{3}x + \frac{1}{2} = \frac{5}{6})$

- 1. Find the LCM of the denominators (3, 2, 6):**
The LCM is 6.
- 2. Multiply both sides by the LCM: $(6 * (\frac{1}{3}x + \frac{1}{2})) = 6 * (\frac{5}{6})$**

3. Distribute: $(6 * \frac{1}{3}x + 6 * \frac{1}{2}) = 6 * \frac{5}{6}$
4. Simplify: $(2x + 3 = 5)$
5. Now solve the two-step equation: Subtract 3 from both sides: $(2x = 2)$. Divide both sides by 2: $(x = 1)$.

Solving Quadratic Equations: Introducing Higher Powers

Quadratic equations are equations where the highest power of the variable is 2. They typically have the form $(ax^2 + bx + c = 0)$, where (a) , (b) , and (c) are constants, and $(a \neq 0)$. Unlike linear equations, quadratic equations can have zero, one, or two real solutions.

Methods for Solving Quadratic Equations

1. Factoring

If a quadratic expression can be factored into

the product of two binomials, we can use the zero product property: If the product of two factors is zero, then at least one of the factors must be zero. This is a very efficient method when it's applicable.

Example: Solve $(x^2 - 5x + 6 = 0)$

1. Factor the quadratic expression: We need two numbers that multiply to 6 and add to -5. These numbers are -2 and -3. So, the factored form is $((x - 2)(x - 3) = 0)$.
2. Apply the zero product property: Set each factor equal to zero: $(x - 2 = 0)$ or $(x - 3 = 0)$.
3. Solve for x: $(x = 2)$ or $(x = 3)$.

2. Using the Quadratic Formula

The quadratic formula is a universal method that works for all quadratic equations, even those that cannot be factored easily. The formula is:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The term $(b^2 - 4ac)$ is called the discriminant. It tells us about the nature of the solutions:

1. If $(b^2 - 4ac > 0)$, there are two distinct real solutions.
2. If $(b^2 - 4ac = 0)$, there is exactly one real solution (a repeated root).
3. If $(b^2 - 4ac < 0)$, there are no real solutions (but there are two complex solutions).

Example: Solve $(2x^2 + 3x - 5 = 0)$

1. Identify a, b, and c: $(a = 2)$, $(b = 3)$, $(c = -5)$.
2. Substitute into the quadratic formula:
$$x = \frac{-3 \pm \sqrt{3^2 - 4(2)(-5)}}{2(2)}$$
$$x = \frac{-3 \pm \sqrt{9 + 40}}{4}$$
$$x = \frac{-3 \pm \sqrt{49}}{4}$$
$$x = \frac{-3 \pm 7}{4}$$

3. Calculate the two possible solutions: $\backslash(x_1 = \frac{-3 + 7}{4} = \frac{4}{4} = 1\backslash) \backslash(x_2 = \frac{-3 - 7}{4} = \frac{-10}{4} = -\frac{5}{2}\backslash)$

3. Completing the Square

This method involves manipulating the equation to create a perfect square trinomial on one side. It's the method used to derive the quadratic formula and can be useful for understanding the structure of quadratic equations.

Example: Solve $\backslash(x^2 + 6x + 5 = 0\backslash)$

1. Move the constant term to the right side:
 $\backslash(x^2 + 6x = -5\backslash)$
2. Take half of the coefficient of the x term, square it, and add it to both sides: The coefficient of $\backslash(x\backslash)$ is 6. Half of 6 is 3, and $\backslash(3^2 = 9\backslash)$. $\backslash(x^2 + 6x + 9 = -5 + 9\backslash)$
3. Factor the left side as a perfect square: $\backslash((x + 3)^2 = 4\backslash)$

4. Take the square root of both sides: $(x + 3 = \pm \sqrt{4})$
5. Simplify and solve for x: $(x + 3 = \pm 2)$
 $(x + 3 = 2 \implies x = -1)$
 $(x + 3 = -2 \implies x = -5)$

Solving Polynomial Equations: Beyond Quadratics

Polynomial equations involve variables raised to higher powers (e.g., x^3 , x^4). Solving these can become progressively more challenging as the degree of the polynomial increases. For degrees higher than two, there isn't a single, simple formula like the quadratic formula.

Strategies for Solving Polynomial Equations

1. **Factoring:** Just like with quadratic equations, if you can factor a higher-degree polynomial, you can use the zero product property. Techniques like factoring by

grouping, difference of squares, and sum/difference of cubes are valuable here.

- 2. Rational Root Theorem: This theorem helps identify potential rational roots (solutions) of a polynomial equation with integer coefficients.**
- 3. Synthetic Division and Polynomial Long Division: These methods are used to test potential roots and to reduce the degree of the polynomial if a root is found. If $(x = r)$ is a root of a polynomial $(P(x))$, then $(x - r)$ is a factor of $(P(x))$, and $(P(x) / (x - r))$ will have a lower degree.**
- 4. Numerical Methods: For very complex polynomials or those with no easily identifiable roots, numerical methods (like Newton's method) are used to approximate solutions.**

Understanding the fundamental principles of equation solving is paramount. As you progress in algebra, you'll encounter more

intricate scenarios, but the core logic of isolating variables through inverse operations and maintaining balance will always hold true.

- 2. Check Your Solutions: After solving an equation, substitute your answer back into the original equation. If both sides are equal, your solution is correct. This is the ultimate verification.**
- 3. Understand the "Why": Don't just memorize**

steps. Understand *why* each operation is performed and how it maintains the equality.

- 4. Practice Regularly: Math skills are built through consistent practice. The more equations you solve, the more comfortable and efficient you will become.**
- 5. Be Patient: Some equations take time and multiple approaches. Don't get discouraged if a solution isn't immediately apparent.**
- 6. Visualize: For linear equations, imagine the number line or the graph. This can provide an intuitive understanding of the solution.**

Common Pitfalls to Avoid

- 1. Sign Errors: These are incredibly common. Double-check your signs when adding, subtracting, multiplying, or dividing.**
- 2. Incorrectly Applying Inverse Operations: Ensure you are using the *correct* inverse operation.**

3. **Forgetting to Perform Operations on Both Sides:** This is the most fundamental rule. Always maintain balance.
4. **Errors in Order of Operations (PEMDAS/BODMAS):** When simplifying or solving, follow the correct order.
5. **Simplification Mistakes:** Combining unlike terms or errors in distributing can lead to incorrect solutions.
6. **Square Root Errors:** Remember that $\sqrt{x^2} = |x|$ and that equations like $x^2 = 9$ have two solutions ($x = 3$ and $x = -3$).

Questions & Answers About how to solve equations in algebra

No	Question	Answer
1	What's the very first step when tackling any algebra equation?	The fundamental first step is to understand what you're trying to achieve: isolate the variable! This means getting the variable (usually 'x' or 'y') all by itself on one side of the equals sign.

2	How do I get rid of numbers that are added to or subtracted from my variable?	Use the opposite operation! If a number is added to the variable, subtract it from both sides of the equation. If a number is subtracted, add it to both sides. This keeps the equation balanced.
3	What's the trick for dealing with numbers multiplied by or divided into my variable?	Again, it's about inverse operations. If the variable is multiplied by a number, divide both sides by that number. If it's divided by a number, multiply both sides by that number.
4	I see parentheses in an equation. What do I do with them?	Usually, you'll need to 'distribute' the number outside the parentheses to each term inside. For example, $2(x + 3)$ becomes $2x + 6$. Then, you can proceed with isolating the variable.
5	What if I have the variable on both sides of the equation?	You need to gather all terms with the variable on one side. Choose either side and move the variable terms from the other side using subtraction or addition, making sure to perform the same operation on both sides.
6	How do I solve equations with exponents, like $x^2 = 9$?	For equations like $x^2 = 9$, you'll take the square root of both sides. Remember that there can be two solutions: the positive and negative root. So, $x = 3$ and $x = -3$.
7	What's a 'linear equation' in algebra?	A linear equation is one where the highest power of the variable is 1. You won't see x^2 , x^3 , etc. They typically form a straight line when graphed.
8	How can I check if my answer to an algebra equation is correct?	The best way to check is to substitute your solution back into the original equation. If both sides of the equation are equal after plugging in your answer, then it's correct!
9	What are 'like terms' and why are they important in solving equations?	Like terms are terms that have the same variable raised to the same power (e.g., $3x$ and $5x$). You can combine like terms by adding or subtracting their coefficients. This simplifies the equation before you start isolating the variable.

1 0	Are there any special cases or 'gotchas' when solving equations?	Yes! Be mindful of negative signs, especially when distributing. Also, remember that dividing by zero is undefined, so if a step requires it, you might have no solution or an error. Always check for extraneous solutions if you've squared both sides of an equation.
